                                                                                                                                                                                                                                                                                                                                                                                                           NOTE: Estimated insert size may differ from sequence length (see http://www.lbgsc.bcm.tmc.edu/docs/Genbank_draft_data.html).

NOTE: This is a 'vorking draft' sequence. It currently consists of 30 contigs. The true order of the pieces is not known and their order in this sequence record is arbitrary Gaps between the contigs are represented as runs of N, but the exact sizes of the gaps are unknown. This record will be updated with the finished sequence
                                                                                                                                                                                                                                                                                                                                                                                as soon as it is available and the accession number be preserved.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              (bases 1 to 191041)

Quality coverage: 4.78 in Q20 bases; sum-of-contigs estimation.
**NOTE: This is a 'working draft' sequence. It currently
**consists of 19 contigs. The true order of the pieces
**is not known and their order in this sequence record is
** arbitrary, Gaps between the contigs are represented as
**runs of N, but the exact sizes of the gaps are unknown.
**This record will be updated with the finished sequence

Detecting the presence or amount of conductin, at protein or nucleic acid levels, is used to diagnose tumours, while agents that (re)activate conductin are used for tumour therapy. Conductin binds to beta-catenin and induces its cytoplasmic degradation, resulting in blockade of the Wnt/Wingless signalling pathway in vertebrates. Conductin also binds to Adenomatous Polyposis Coli (APC) fragments and, in conjunction with APC, acts as a tumour suppressor.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           anti-tumour activity. Detecting the presence or amount of conductin, at protein or nucleic acid levels, is used to diagnose tumours, while agents that (re)activate conductin are used for tumour therapy. Conductin binds to beta-catenin and induces its cytoplasmic degradation, resulting in blockade of the Wnt/Wingless signalling pathway in vertebrates. Conductin also binds to Adenomatous Polyposis Coli (APC)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    This invention describes a novel

                                                                                                                                                                                                                                                                                                                                                                                                                                    1772
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       type Axin and homologues of Axin are useful for treating subjects who are likely to develop cancer (thyroid carcinomas). The nucleic acids are also useful for diagnosing cancer and for detecting mutations in cancerous cells. Wild type Axin, its antisense molecule and identified compounds form pharmaceutical compositions in the treatment of cancer. The compositions are also useful for treating cancer by inhibiting tumorigenesis (by inducing degradation of beta-catenin). The nucleic acid encoding Axin acts through

The OREX sequences have activities such as: cytostatic; hepatotropic; vulnerary; antipsoriatic; antiparkinsonian; mootropic; neuroprotective; osteopathic; anticonvulsant; antiarthritic; immunosuppressant; immunostimulant; cardiant; thrombolytic; coagulant; vasotropic; antidabetic; hypotensive; dermatological; immunosuppressive; antiinflammatory; antibacterial; antifungal; antifungal; antithromoty; antibacterial; antivital; antifungal; antifungal; anticonvold; and antianaemic. The sequences can be used for determining the presence of or predisposition to, or preventing or treating pathological conditions associated with an OREX-associated disorder. The nucleic acids can be used to express orex proteins in gene therapy vectors. The proteins and nucleic acids may be used to treat cancers, proliferative disorders, neurodegenerative disorders, osteoarthritis, graft vs host disease, cardiovascular disease, disorders, asthma, altergies, aplastic anaemia, burns, wounds, bone and cartilage damage, nocturnal haemoglobinuta, antiinflammatory disease; to

                                                                                                                                                                                                                                                                                                              Nucleic acids encoding mutant and wild type Axin and coligonucleotides derived from them are useful for detecting mutations in the Axin gene and for determining whether a subject is likely to develop cancer (including breast, colorectal, gastrointestinal, esophageal, carcinomas or melanomas). The wild type Axin and homologues of Axin are useful for treating subjects who are likely to develop cancer (thyroid carcinomas). The nucleic acids are also useful for diagnosing cancer and for detecting mutations in cancerous cells. Wild type Axin, its antisense molecule and identified compounds form pharmaceutical compositions in the treatment of cancer. The compositions are also useful for treating cancer by inhibiting tumorigenesis (by inducing degradation of beta-catenin). The nucleic acid encoding Axin acts through cancer negative regulation of the Wnt pathway in the Nieuwkoop Center.

Host cells expressing the polypeptides are useful for screening for ligands of an imidazoline receptor. Restriction fragments of the polynucleotide are useful as labeled probes for isolating and identifying DNA material encoding polypeptides that are receptive to imidazoline compounds. The isolation of polynucleotides encoding the imidazoline receptive polypeptides have immunological and ligand binding properties, which enable identification of agents having greater potency and/or more selectivity for these receptors.

                                                                                                                                                                                                                                                                                                                                                                               The present invention describes a method for monitoring differential CC expression of genes in a first filamentous fungal (FF) cell relative to cx expression of the same genes in one or more second filamentous fungal CC cells. The method uses fluorescence-labeled nucleic acids isolated from the FF cells and a substrate of expressed sequence tags (EST). The ESTS CA are used in the methods for monitoring differential expression of genes CC in a first filamentous fungal (FF) cell relative to expression of the composition of genes from FF cells allows the production of the global expression of genes from FF cells allows the production of potential of the microorganisms to be improved. New genes may be consisted and gene copy number variation and stability can be composited and gene copy number variation and stability can be comproyenesis, recombination, metabolic or catabolic pathway engineering. CC using ESTs provides several advantages over genomic or random cDNA CC clones including elimination, metabolic or catabolic pathway engineering. CC using ESTs provides several advantages over genomic or random cDNA CC clones including elimination of the gene products to facilitate consists of the results. F07478 to FF1247 represents ESTs from Aspergillus niger; CC unalysis of the results. F07478 to FF1247 represents ESTs from Aspergillus niger; CC E15337 represents ESTs from Aspergillus niger; and CC entered to the present invention.

A method for diagnosing cancer or determining p53 status in a sample suspected for being neoplastic comprises comparing the level of transcription of an RNA transcript in a first sample (s1) of a first tissue (t1) to the level of transcription of the transcript in a second sample (s2) of a second tissue (s2), where s1 is suspected of being neoplastic and s2 is a normal human tissue (of the same type) and the transcript is identified by a tag; and categorizing s1 as neoplastic or as having a mutant p53 when transcription is found to be the same or lower in the first, than in s2. The methods and products can be used to determine p53 status, to diagnose cancer and to evaluate cytotoxicity or carcinogenicity of a test agent. X86265-75 encode human PIG proteins.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The present sequence represents the human longevity assurance gene 1 (LAGI), designated LAGIHs. The LAGIHs cDNA was isolated from total brain mRNA. The LAGI protein, or proteins with at least 25-30% homology to the LAGIHs protein, is administered to increase the longevity of a human cell: Expression of these polypeptides is used to increase tolerance of human cells to cellular stresses, such as starvation or acidic pH (5-5.5). The LAGI proteins are also used for increasing reproductive capacity of human cells. LAGI polynucleotides can be used as probes for detecting LAGI from different species, as the LAGI gene is highly conserved across the spectrum of eukaryotes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                    Sequence 10384 BP; 2135 A; 2839 C; 3598 G; 1812 T; 0 other;

                                                                                                                                                                                                                                                                                                                                                                                                                                            sequences given in Q32578-79. The sequences were then amplified using primer pairs. The cDNA sequences isolated represent different alleles of the same region of the HCV gene. Sequence comparisons of these clones showed that it is possible for a patient to carry more than one HCV strain at one time. See also Q32436.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The sequences given in Q32483-501 are various clones which were used in the isolation of the NS2-NS4 regions of the Hepatitis C Virus (HCV) gene of the invention (see also Q32442 and Q32472-82). These sequences were isolated from the serum of a patient suffering from hepatitis C (HC). The isolated RNA sequences were converted into CDNA using transcriptase in the presence of one of the primer sequences given in 032578-79. The sequences were then amplified
                                                                                     transcriptase; cDNA;

These sequences were isolated from the serum of a patient suffering from hepatitis C (HC). The isolated RNA sequences were converted into CDNA using transcriptase in the presence of one of the primer sequences given in 03253-64. The sequences were then amplified using primer pairs. The cDNA sequences isolated represent different alleles of the same region of the HCV gene. Sequence comparisons of these clones showed that it is possible for patient to carry more than one HCV strain at one time. See also

The sequences were then amplified using primer pairs. The cDNA sequences isolated represent different alleles of the same region of the HCV gene. Sequence comparisons of these clones showed that it is possible for a patient to carry more than one HCV strain at one time. See also Q32436.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The sequences given in Q32483-501 are various clones which were used in the isolation of the NS2-NS4 regions of the Hepatitis C virus (HCV) gene of the invention (see also Q33442 and Q32472-80). These sequences were isolated from the serum of a patient suffering from hepatitis C (HC). The isolated RNA sequences were converted into cDNA using transcriptase in the presence of one of the primer sequences given in Q32578-79. The sequences were then amplified using primer pairs. The cDNA sequences isolated represent different alleles of the same region of the HCV gene. Sequence comparisons of these clones showed that it is possible for a patient to carry more than one HCV strain at one time. See also Q32436.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present sequence is the gene encoding the mouse Kv6.2 monomer, which is an alpha subunit of heteromeric voltage-gated potassium channel. It is isolated from brain tissue and maintains the resting potential and controls the excitability of a cell. Kv6.2 polypeptide can be used to identify compounds, that modulate the ion flux through heteromeric voltage-gated potassium channels. Such modulators are used as neuroprotective agents and for treating CNS disorders, such as migraines, hearing and vision problems, psychotic disorders and seizures. It can also be used as reporter molecules in assays and to produce antibodies. Kv6.2 DNA sequence can be used to produce specific primers or probes

                                                                                                                                                                                                                                                                                                           The sequences given in Q32483-501 are various clones which were used in the isolation of the NS2-NS4 regions of the Hepatitis C virus (HCV) gene of the invention (see also Q32442 and Q32472-82). These sequences were isolated from the serum of a patient suffering from hepatitis C (HC). The isolated RNA sequences were converted into CDNA using transcriptase in the presence of one of the primer sequences given in Q32578-79. The sequences were then amplified using primer pairs. The CDNA sequences isolated represent different alleles of the same region of the HCV gene. Sequence comparisons of these clones showed that it is possible for a patient to carry more than one HCV strain at one time. See also Q32436.
                                                                                                                                                                                                                                                                                    Sequence 3564 BP; 668 A; 1064 C; 1046 G; 786 T; 0 other;
